

River Journey

<p>Source</p> 	<p>The start of a river is its source. It is where it begins its journey. This could be a spring on a hillside, a mountain, a lake, or a bog or marsh. A river may have more than one source.</p>
<p>Waterfall</p> 	<p>An area where water flows over a vertical drop or a series of steep drops in the course of a river. Soft rock is eroded by water which leaves a hard rock ledge from which the water falls.</p>
<p>Meanders</p> 	<p>A curve in a river which forms a snake-like pattern. The river erodes sediment on the outside of the curves and drops it on the inside of curves due to water moving fastest on the outside of a turn.</p>
<p>Mouth</p> 	<p>The end of a river where it flows into the sea, another river or a lake is known as the mouth of the river. Much of the river's gravel, sand, silt and clay are deposited here.</p>
<p>Delta</p> 	<p>A wide muddy or sandy area where some rivers meet the sea at a very slow speed, or often in still/stagnant water. The river slows and drops all the sediment that it was carrying, creating a wide, marshy area.</p>

River Management

<p>Drinking Water</p> 	<p>Rivers, lakes or reservoirs may sometimes look clean but they are often filled with bacteria which can make you sick. It is therefore treated to make sure it meets safe drinking standards before being pumped to homes.</p>
<p>Sampling and Research</p> 	<p>Water sampling is the process of taking a water for testing. It is also used to test the health of the river and to find out if pollution, such as chemical from farming, are present.</p>
<p>Dams</p> 	<p>A dam is a barrier that stops or restricts the flow of water or underground streams. Reservoirs created by dams not only prevent floods but also provide water for activities such as irrigation, drinking water and industrial use.</p>

Rivers

A river is the path that water takes as it flows along a channel downhill with banks on both sides and a bed at the bottom. If there is lots of rain, snow or melting ice, rivers often overflow beyond the top of their banks and begin to flow onto floodplains at either side.

Key Vocabulary

confluence
erosion
estuary
meander
source
tributary

The Nile

The Nile begins as two rivers. The White Nile comes from Lake Victoria in Uganda and the Blue Nile starts in the Ethiopian Highlands. They join together in Sudan to form one river. The River Nile brings water to the Sahara Desert and, for thousands of years, it has been used to water crops (irrigation). Rivers were also important trade routes. It eventually reaches the sea but due to the heat, much of it evaporates before it gets there. It also splits into many smaller rivers forming a delta.

Erosion and Deposition

Erosion is when materials, like soil or rocks, are moved by water. All these materials are called sediments. Deposition is when those sediments are deposited, or dropped off, in a different place. When rivers are flowing fast, they knock bits of earth from the banks and bed of the river (its sides and bottom) and carry it downstream with them.

World's Longest Rivers

	Nile – 6695km (Africa)
	Amazon – 6516km (South America)
	Yangtze – 6380km (Asia)
	Mississippi/Missouri – 5969km (North America.)
	Murray/Darling – 3672km (Australia)
